CHILDREN with LEUKAEMIA Scientific Conference 6-10 September 2004
Health implications of particles

OCCUPATIONAL EXPOSURE

‘Classic’ occupational diseases, e. g. pneumoconiosis, emphysema, chronic bronchitis, pneumonitis, lung cancer (quartz).

Typical exposures: mg/m³

AMBIENT EXPOSURE (PM₁₀ / PM₂.₅)

Acute: asthma attacks, exacerbations of chronic obstructive pulmonary disease (COPD) and cardiovascular disease

Chronic: immunological effects, cancer

Typical exposures: µg/m³
Quartz and lung cancer

- Epidemiological studies (reviewed by IARC 1997)

- Toxicological studies in rats

**Tumour formation in rat inhalation studies is associated with durability of the material (biopersistence) → Poorly soluble particles (PSP)**
Pathogenesis

Exposure → inflammation → fibrosis → cancer?
Particles and inflammation

→ Accumulation of inflammatory cells
   *Neutrophils, macrophages (chronic inflammation)*

→ Increased permeability of epithelium, cell damage

→ Epithelial hyperthrophy and hyperplasia, fibrosis

→ Expression of cytokines, chemokines and adhesion molecules
   
   *e.g.* Tumor Necrosis Factor-alpha (TNF), interleukin-1 (IL-1)
   Macrophage Inflammatory Protein-2 (MIP-2), IL-8,
   Intercellular Adhesion Molecule-1 (ICAM-1)
Inflammatory genes:
- TNF
- IL-1, IL-1, IL-22
- IL-6, IL-6, IL-8
- iNOS, COX-2
- GM-CSF, G-CSF, G-CSF
- ICAM-1
- MIP-1α, MIP-2α
- RANTES, MCP-1

Particles

"Oxidative stress"

Nuclear factor kappa B (NF-κB)

A crucial transcription factor in particle-induced inflammation?

Nuclear factor kappa B (NFκB)  
A crucial transcription factor in particle-induced inflammation?

Neutrophil influx by quartz is preceded by Nuclear Factor kappaB (NFκB) activation in bronchoalveolar lavage macrophages

Quartz treatment causes NFκB activation in macrophages as well as in lung epithelial cells (t=72h)

Proposed mechanisms for carcinogenicity of poorly soluble particles (PSP)

PSP exposure

Chronic inflammation and release of ROS/RNS

Genotoxicity ↔ Cell proliferation

Tumour formation

**In vivo genotoxicity of particles (quartz)**

Single *intratracheal* instillation (2 mg quartz/rat, 5 animals per group)

- Determination of inflammation and DNA damage at 3 days after instillation

- **Lavage, isolation**
  - BAL: Inflammatory cell counts, markers of inflammation and toxicity

- **Digestion**
  - Trypsin

- **Percoll gradient**
  - surfactant epithelial cells

- **EPI:** DNA damage (comet assay)

- Purification
  - Harvesting
  - & Analysis
DQ12 Quartz 2 mg/rat i.t. t = 72h

- Recruitment and activation of neutrophils
- DNA damage in lung epithelium (comet assay following isolation)

Ambient particulate matter (PM)

EPIDEMIOLOGICAL OBSERVATIONS

- Exacerbations of airways disease in COPD and asthma (Pope and Dockery, 1999)
- Cardiovascular deaths/hospital admissions (Schwartz and Morris, 1995)
  - Cancer (Beeson et al., 1998; Pope et al., 2002)
  - 8 % increase with a 10 µg/m³ change in PM 2.5

Susceptible groups

- Elderly, diseased individuals,...
- CHILDREN (asthma, allergies, cancer ?)
Carcinogenesis of PM?
PM causes inflammation

In vitro studies
→ Activation of NFκB pathway, enhanced expression of proinflammatory cytokines (e.g. TNF, MIP-2, IL-6, IL-8)
  (e.g. Becker et al. Toxicol Appl Pharmacol 1996; Frampton et al., Am J Physiol 1999)

Inhalation / intratracheal instillation studies in rats
→ Enhanced cytokine/chemokine expression, neutrophil influx
  (e.g. Shukla et al., Am J Respir Cell Mol Biol 2000; Schins et al., Toxicol Appl Pharmacol 2004)

Human volunteer studies (CAPS inhalation, intratracheal instillation of PM)
→ Role for transition metals, ultrafine particles and/or endotoxin
  (e.g. Ghio and Devlin, AjRCCM 2002; Schaumann et al. AjRCCM 2004)

→ Role for transition metals, ultrafine particles and/or endotoxin
Ambient exposure to PM and cancer?

**Exposure to ambient PM**

- Toxicological evidence (animal experiments & volunteer studies)
- Epidemiology observations

**Inflammation**

? \rightarrow \text{Carcinogenicity}

Experimental observations with PSP

Important research questions:

- Investigation of chronic effects of PM (inflammation, tumorigenesis?)
- Experiments with model PM to determine the role of constituents and/or characteristics of PM that drive inflammation and genotoxicity
Primary particles (predominantly traffic/combustion)
→ ultrafine particles i.e. <100nm (poorly soluble)
→ organics e.g. polycyclic aromatic hydrocarbons (PAH)
→ transition metals (Fe, Ni, Cu, V, Zn, Cr, ..)

Secondary particles (atmospheric chemistry: SO$_2$, NO$_x$, ammonia, sunlight)
→ Ammonium sulphates, nitrates, chlorides

Crustal minerals (e.g. wind blown)
→ mineral rich: aluminium silicate clays, soil particles

Biologically-derived material
→ Endotoxin
→ Fungal spores, plant parts, bacteria, etc.

Primary genotoxicity?
PAH, nitro-PAH, metals, ketones, carboxylic acids, aldehydes, peroxides....
PM and DNA damage
Oxidative DNA damage by PM

Damage to ‘naked’ DNA
(plasmid unwinding)

Damage to ‘naked’ DNA
(8-HOdG immunodotblot)

**Fenton reaction:**

\[ \text{Fe}^{2+} + \text{H}_2\text{O}_2 + \text{H}^+ \rightarrow \text{Fe}^{3+} + \text{H}_2\text{O} + \cdot \text{OH} \]

**Reactive oxygen species (ROS) generation by PM**

PM

PM + DFO

Role of PAH in genotoxicity of PM?

Mutagenicity of airborne PAH has been clearly established

- Effects of PM filter extracts (organic solvents) in Ames test, SCE test, etc

- Extracts cause bulky DNA adducts in vitro and in vivo

Particles are carriers of PAH into the lungs

- Availability of PAH from PM, in vitro, in vivo?
Bioavailability of PAH from carbon black particles - Adduct formation in A549 human lung epithelial cells -

- Control
- Blank (DMSO)
- CB -original
- CB -extracted
- Extract of CB
- EPA mixture
- CB (extracted) - coated with EPA-mix

Number of adducts per 10^8 n.t.

Red: spot
Yellow: DRZ
PM sampling using high volume cascade impactor (HVCI) in Amsterdam, Athens, Barcelona, Duisburg, Helsinki & Prague

Coarse PM, fine PM, ultrafine particles.

Chemical characterisation e.g. metals, PAH, endotoxin

Inflammation & genotoxicity: in vitro and in vivo
- *in vitro* (macrophages, lung epithelial cells)
- *in vivo* (SHR rats, whole lung, isolated epithelial cells)
PAH-DNA adduct formation by PM in lung epithelial cells \textit{in vitro} \hfill (^{32}\text{P}-postlabelling)

NFκB, TNF, MIP-2, NO

Target cell

ROS

ONOO^-

8-OHdG

Cyp/EH

Proposed mechanisms of genotoxicity of PM
(studies with model PM)
PM and childhood cancers

Carcinogenesis beyond the respiratory tract?
Induction of systemic oxidative stress and genotoxicity

1. Biomarker studies:

- Enhanced oxidative DNA damage (8-OHdG) in peripheral blood leukocytes, and blood antioxidant status of individuals with (chronic) occupational dust exposure, e.g. coal miners (e.g. Schins et al., Int Arch Occup Env Hyg 1995; Schins et al., Biomarkers 1999)

- Correlation between personal PM2.5 exposure and oxidative DNA damage (e.g. comet) in peripheral blood leukocytes (e.g. Sorensen et al., 2003)

2. Toxicological studies (animal models):

- Particles (inhalation, instillation) elicit genotoxic/mutagenic effects outside the lungs: Endpoints include DNA strand breaks and oxidative damage, bulky DNA adducts, chromosomal aberrations, sister chromatid exchanges).

- Various tissues/organs involved such as peripheral blood/bone marrow cells, liver, colons
Systemic effects of ultrafine PM:
- Translocation of particles -

Inhaled/instilled particles translocate from the lungs into the blood → implicated in the observed association between PM exposure and cardiovascular effects: (e.g. Nemmar et al. 2001; 2003; Kreyling et al., 2002)

Carbon particles (C14, ultrafine) are found in the brain of rats following inhalatory exposure → translocation of particles along the olfactory nerves has been proposed (Oberdorster et al., Inhal Toxicol 2004)
Germline mutagenesis

Germline mutation rates at expanded-simple-tandem repeat (ESTR) DNA loci in mouse pedigrees in association with urban/industrial air pollution (TSP = 40 – 115µg/m³; PAH = 2– 30µg/m³)

Reduction following particulate-air filtration (> 0.1µm)

Particulate air pollution can cause genetic damage in germ cells & transgenerational effects
How may particles impact on carcinogenesis in various organs other than lungs?

PM (ultrafine component) can translocate from the airways into the blood and thus reach various target cells/tissues. Possible implications:

- Direct genotoxic effects of particles (surface reactivity, ROS production)
- Induction of inflammation, apoptotic and/or (compensatory) proliferation
- Carrier effect: Systemic delivery of mutagens/carcinogens (e.g. PAH)

Particles activate signalling pathways (inflammation/proliferation) within the lung

- Systemic release of mediators (e.g. cytokines, growth factors, ROS) may impact on processes involved in carcinogenesis (e.g. apoptosis, proliferation)
